1 Introduction

1.1 Definitions

Let's consider $V = \{v_1, \dots, v_{|V|}\}$ a set of vertices. We denote by $|V|$ the cardinality of the set V . Let's define the function:

$$X : \mathbb{N} \rightarrow \mathbb{N} : n \mapsto \frac{n(n-1)}{2} = \binom{n}{2}.$$

Definition 1.1. For $(\alpha, \beta) \in \mathbb{N}^2$, if $\beta \geq \alpha$, we define:

$$\llbracket \alpha, \beta \rrbracket := \{n \in \mathbb{N} \text{ s.t. } \alpha \leq n \leq \beta\}.$$

Definition 1.2. An undirected graph Γ is denoted $\Gamma = (V, E)$ for V its vertices set, and E its edges set, with $E = \{e_1, \dots, e_{|E|}\}$ and $\forall i \in \llbracket 1, |E| \rrbracket : e_i = \{v_{i_1}, v_{i_2}\}$ for $1 \leq i_1, i_2 \leq |V|$ with $i_1 \neq i_2$ (i.e. loops are not tolerated).

For a given graph $\Gamma = (V, E)$, we also write $V = V(\Gamma)$ and $E = E(\Gamma)$.

Remark. $|E|$ is usually denoted as m , and $|V|$ is sometimes denoted as n . Both these numbers are non-negative integers.

Definition 1.3. The set of all the existing graphs having given vertices set V is denoted by $\Gamma(V, \cdot)$. For $m \in \mathbb{N}$, we denote $\Gamma_m(V, \cdot)$ the subset of $\Gamma(V, \cdot)$ such that :

$$\forall \Gamma \in \Gamma_m(V, \cdot) : |E(\Gamma)| = m.$$

Remark. We observe that:

$$\Gamma(V, \cdot) = \bigsqcup_{m \in \mathbb{N}} \Gamma_m(V, \cdot).$$

Definition 1.4. For every $n \in \mathbb{N}$, we define \mathcal{K}_n as the *complete graph* of size n , such that:

$$E(\mathcal{K}_n) = \{\{v_i, v_j\} \text{ s.t. } v_i \neq v_j \text{ and } (v_i, v_j) \in V^2\}.$$

Lemma 1.5. For a graph $\Gamma = (V, E)$, we have $|E| \leq X(|V|)$.

Proof. We know that $\Gamma = (V, E) \leq \mathcal{K}_{|V|}$, and $\mathcal{K}_{|V|}$ has exactly $X(|V|)$ edges (vertex v_i is connected to vertices v_{i+1} to $v_{|V|}$, so the number of edges is equal to $\sum_{i=1}^{|V|} (|V| - i) = \sum_{i=0}^{|V|-1} i = X(|V|)$). \square

Lemma 1.6. For given vertices set V and fixed number of edges $m \in \mathbb{N}$, we have:

$$|\Gamma_m(V, \cdot)| = \begin{cases} \binom{X(|V|)}{m} & \text{if } m \leq X(|V|) \\ 0 & \text{else} \end{cases}.$$

Proof. There are $X(|V|)$ edges $e = \{v_i, v_j\}$ which exist in $\mathcal{K}_{|V|}$. A graph Γ in $\Gamma_m(V, \cdot)$ has m of these $X(|V|)$ edges. The amount of such graphs is then $\binom{X(|V|)}{m}$. \square

Corollary 1.7. For given vertices set V , we have $|\Gamma(V, \cdot)| = 2^{X(|V|)}$.

Proof. Since $\Gamma = (V, \cdot)$ is given by a disjoint union over m , its cardinality is equal to the sum of the individual cardinalities:

$$|\Gamma(V, \cdot)| = \sum_{m \in \mathbb{N}} |\Gamma_m(V, \cdot)| = \sum_{k=0}^{X(|V|)} |\Gamma_k(V, \cdot)| = \sum_{k=0}^{X(|V|)} \binom{X(|V|)}{k} = 2^{X(|V|)}.$$

\square

Definition 1.8. A graph $\Gamma = (V, E)$ is said to be connected if for each $v, w \in V$, there exists a path between v and w . We denote by $\chi(V, \cdot)$ the set of all connected graphs having vertices set V . Again, for $m \in \mathbb{N}$, we denote by $\chi_m(V, \cdot) := \chi(V, \cdot) \cap \Gamma_m(V, \cdot)$ the set of connected graphs having m edges.

Remark. $\chi(V, \cdot) \subset \Gamma(V, \cdot)$, and:

$$\chi(V, \cdot) = \bigsqcup_{m \in \mathbb{N}} \chi_m(V, \cdot).$$

Lemma 1.9. For $m < |V| - 1$ or $m > X(|V|)$, we have $\chi_m(V, \cdot) = \emptyset$.

Proof. For $m > X(|V|)$, we know that $\Gamma_m(V, \cdot) = \emptyset$. As $\chi_m(V, \cdot) \subset \Gamma_m(V, \cdot)$, we know that $\chi_m(V, \cdot) = \emptyset$.

For $m < |V| - 1$, let's notice firstly that a cyclic graph needs at least $|V|$ edges: for a cyclic graph, each vertex degree must be at least 2. We can deduce:

$$2|E| = \sum_{v \in V} \deg(v) \geq 2|V|.$$

Thus $|V| \geq |E|$ for a cyclic graph. Let's assume (*ad absurdum*) that there exists $\Gamma = (V, E) \in \chi_m(V, \cdot)$. Therefore Γ is acyclic. By definition of $\chi_m(V, \cdot)$, we know that Γ is connected. But an acyclic and connected graph is a tree, and a tree has exactly $|V| - 1 \not\geq m$ edges, which is a contradiction. Therefore, $\chi_m(V, \cdot) = \emptyset$. \square

Definition 1.10. Let's define the function:

$$\mu : \mathcal{P}(V) \rightarrow \llbracket 1, |V| \rrbracket : W \mapsto \mu(W) := \inf \{i \in \llbracket 1, |V| \rrbracket \text{ s.t. } v_i \in W\}$$

representing the lowest index of a vertex present in a given subset of $W \subset V$.

Remark. This definition depends then on the order of the elements in V , but is well defined for any labeling of V .

Definition 1.11. For every $W \in \mathcal{P}(V)$, we define $\Delta_W : \Gamma(V, \cdot) \rightarrow \Gamma(W, \cdot) : \Gamma \mapsto \Gamma'$ such that:

$$E(\Gamma') = \{\{v_i, v_j\} \in E \text{ s.t. } v_i, v_j \in W\},$$

and $V(\Gamma') = W$.

Let's call Δ_W the *restriction to subset W operator*.

1.2 (Largest) Connected Components

Definition 1.12. We define the *connected component of vertex $v_i \in V$ in graph $\Gamma = (V, E)$* by the biggest subset (in the sense of inclusion) W of V such that $v_i \in W$ and $\Delta_W(\Gamma) \in \chi(W, \cdot)$.

Definition 1.13. For graph $\Gamma \in \Gamma(V, \cdot)$, we define $|LCC(\Gamma)|$ by:

$$|LCC(\Gamma)| := \max_{W \in \mathcal{P}(V)} |W| \mathbb{I}_{\chi(V, \cdot)}(\Delta_W(\Gamma)),$$

for \mathbb{I}_X being the characteristic function defined by $\mathbb{I}_X(x) = 1$ if $x \in X$ and 0 otherwise.

We then define the *largest connected component of the graph $\Gamma = (V, E)$* as:

$$LCC(\Gamma) := \underset{\substack{W \in \mathcal{P}(V) \\ |W| = |LCC(\Gamma)|}}{\operatorname{argmin}} \mu(W).$$

Definition 1.14. For $k \in \mathbb{N}$, we define $\Lambda_k(V, \cdot)$ to be the set of all graphs $\Gamma \in \Gamma(V, \cdot)$ such that $|LCC(\Gamma)| = k$. Again, for $m \in \mathbb{N}$, we define $\Lambda_k^m(V, \cdot) := \Lambda_k(V, \cdot) \cap \Gamma_m(V, \cdot)$.

Remark. The notations here are consistent since for Γ a graph, $|\text{LCC}(\Gamma)|$ corresponds indeed to the cardinality of $\text{LCC}(\Gamma)$.

Furthermore, this definition of largest connected component allows to define uniquely the LCC, even though a graph Γ has several connected component of same size. For example, following graph has two connected component of size 2, i.e. $\{1, 2\}$ (in red) and $\{3, 4\}$ (in blue).

Figure 1: Graph $([1, 4], \{\{1, 2\}, \{3, 4\}\})$

Nevertheless, the LCC operator yields $\{1, 2\}$ since it minimizes the lowest id of element in connected component (1 for this graph).

Remark. Since $\Lambda_k(V, \cdot) = \bigsqcup_{m=0}^{X(V)} \Lambda_k^m(V, \cdot)$ and:

$$\Gamma(V, \cdot) = \bigsqcup_{k=1}^{|V|} \bigsqcup_{m=0}^{X(V)} \Lambda_k^m(V, \cdot),$$

we want to know what is $|\Lambda_k^m(V, \cdot)|$ equal to.

Definition 1.15. Let's declare a new random variable $\mathcal{G}(V, m)$, a graph uniformly distributed in $\Gamma_m(V, \cdot)$, thus such that:

$$\forall \Gamma \in \Gamma_m(V, \cdot) : \mathbb{P}[\mathcal{G}(V, m) = \Gamma] = \frac{1}{|\Gamma_m(V, \cdot)|} = \frac{1}{\binom{X(V)}{m}}.$$

1.3 Objectives

The objective now is to find an expression for $|\Lambda_k^m(V, \cdot)|$ since we are looking for:

$$\mathbb{P} \left[|\text{LCC}(\mathcal{G}(V, m))| = k \right] = \frac{|\Lambda_k^m(V, \cdot)|}{|\Gamma_m(V, \cdot)|}.$$

Let's denote this value $p_k := \mathbb{P} \left[|\text{LCC}(\mathcal{G}(V, m))| = k \right]$.

2 Preliminary Results

The general idea in order to determine $|\Lambda_k^m(V, \cdot)|$ is to insert a connected component of size k on vertices set V , and then to complete the graph placing $m - k$ vertices without making a connected component of size $\geq k$.

2.1 $|\Lambda_{k=1}(V, \cdot)|$

It is trivial to tell $|\Lambda_1^m(V, \cdot)| = \delta_0^{m1}$, i.e. equals one if $m = 0$ and equals zero if $m > 0$: a graph having at least one edge, cannot have a largest connected component of size 1 because if $e = \{v_i, v_j\}$ is an edge in E , then $\{v_i, v_j\} \subset V$ is a connected component of size 2.

2.2 Upper Boundary of m for $|\Lambda_k^m(V, \cdot)|$

Lemma 2.1. For $\Gamma \in \Gamma(V, \cdot)$ a graph and $k \in \llbracket 1, |V| \rrbracket$, if there exists a vertex $v \in V$ such that $\deg(v) = k$, then $|\text{LCC}(\Gamma)| \geq k + 1$.

Proof. Take $v \in V$ such that $\deg(v) = k$. There exist $\{v_{i_1}, \dots, v_{i_k}\} \subset V$ such that:

$$\forall j \in \llbracket 1, k \rrbracket : \{v, v_{i_j}\} \in E.$$

Thus $\{v, v_{i_1}, \dots, v_{i_k}\}$ is a connected component of size $k + 1$. Thus the largest connected component must have size at least that big. \square

Proposition 2.2 (Upper boundary of edges amount). For $k \in \llbracket 1, |V| \rrbracket$, and $m > \frac{|V|(k-1)}{2}$, we have $\Lambda_k^m(V, \cdot) = \emptyset$.

Proof. Take $m > \frac{(k-1)|V|}{2}$, and $\Gamma = (V, E) \in \Gamma_m(V, \cdot)$. Take $\mathcal{V}_k := \{v \in V \text{ s.t. } \deg(v) \leq k-1\}$. Let $\Gamma' = (\mathcal{V}_k, E')$ be defined by $\Delta_{\mathcal{V}_k}(\Gamma)$. We know that:

$$2|E'| = \sum_{v \in \mathcal{V}_k} \deg(v) \leq (k-1)|\mathcal{V}_k| \leq (k-1)|V|.$$

We deduce that $|E'| \leq \frac{(k-1)|V|}{2} < m = |E|$. Thus $|E| \not\geq |E'|$, and this implies that there exists $v \in V$ such that $\deg(v) \geq k$. By previous lemma, largest connected component size must be at least $k + 1$. \square

Remark. We can understand this upper boundary as $m > \frac{|V|(k-1)}{2} = \frac{|V|}{k} \frac{k(k-1)}{2} = \frac{|V|}{k} \cdot X(k)$. So in order to have a LCC of size k , edges can be distributed to make $\left\lfloor \frac{|V|}{k} \right\rfloor$ complete graphs having each $X(k)$ edges. The maximum amount of edges is then given by $\frac{|V|(k-1)}{2}$.

2.3 $|\Lambda_{k=2}(V, \cdot)|$

Example of size 2 is a bit more complicated:

$$\forall m \in \left[1, \left\lfloor \frac{|V|}{2} \right\rfloor\right] : |\Lambda_2^m(V, \cdot)| = \begin{cases} \frac{1}{m!} \prod_{k=0}^{m-1} \binom{|V|-2k}{2} & \text{if } m \leq \frac{|V|}{2} \\ 0 & \text{else} \end{cases}.$$

Proof. For $m > \frac{|V|}{2}$, result is shown in Proposition 2.2. The part $\prod_{k=0}^{m-1} \binom{|V|-2k}{2}$ corresponds to the choice of m edges without making a connected component of size ≥ 3 .

¹ δ_i^j is the Kronecker delta operator.

$\binom{|V|-2\cdot 0}{2}$ is the choice of the first edge (two vertices) among $|V|$ vertices, $\binom{|V|-2}{2}$ is the choice of the second edge (two vertices) among the $|V| - 2$ vertices left, etc. At step ℓ , only $|V| - 2(\ell - 1)$ vertices are available because two are selected per step, and a selected vertex cannot be used again, otherwise its degree would be ≥ 2 , and then the largest component size would be ≥ 3 .

The $\frac{1}{m!}$ comes from the fact that the order the edges are selected doesn't matter (so for each choice of m edges, there are $m!$ permutations of these). \square

Remark. This can also be expressed as:

$$|\Lambda_2^m(V, \cdot)| = \frac{1}{m!} \frac{|V|!}{2^m (|V| - 2m)!},$$

by simplification of the product.

2.4 Generalization

Definition 2.3. Let's denote equally $\Lambda_k^m(n) \equiv |\Lambda_k^m(V, \cdot)|$ for V such that $|V| = n$.

This notation allows to lighten the expressions.

Lemma 2.4. The sets $\chi_\ell(V, \cdot)$ and $\Lambda_{|V|}^\ell(V, \cdot)$ are equal.

Proof. A graph Γ is connected if and only if its largest connected component contains all its vertices, i.e. $\text{LCC}(\Gamma) = V$.

This is equivalent to say that $|\text{LCC}(\Gamma)| = |V|$ since $\forall W \in \mathcal{P}(V) : |W| = |V| \Rightarrow V = W$:

$$\forall W \in \mathcal{P}(V) : \left| \left\{ \widetilde{W} \in \mathcal{P}(V) \text{ s.t. } |W| = |\widetilde{W}| \right\} \right| = \binom{|V|}{|W|},$$

and $\binom{|V|}{|V|} = 1$, thus $\{W \in \mathcal{P}(V) \text{ s.t. } |W| = |V|\} = \{V\}$. \square

2.5 Decomposing set $\Lambda_k(V)$

Definition 2.5. For $k \in \mathbb{N}$, and $\alpha \in \mathbb{N}$, we define:

$$\Lambda_{k,\alpha}(V, \cdot) := \left\{ \Gamma \in \Lambda_k(V, \cdot) \text{ s.t. } \left| \left\{ W \in \mathcal{P}(V) \text{ s.t. } \Delta_W(\Gamma) \in \chi(W) \text{ and } |W| = |\text{LCC}(\Gamma)| \right\} \right| = \alpha \right\},$$

the class of all graphs in $\Lambda_k(V, \cdot)$ having exactly α connected components of maximum size.

Again, for $m \in \llbracket 0, X(|V|) \rrbracket$, we define $\Lambda_{k,\alpha}^m(V, \cdot)$ by $\Lambda_k^m(V, \cdot) \cap \Lambda_{k,\alpha}(V, \cdot)$.

Remark. Even though several connected components of maximum size do exist in a graph, *the one* LCC is still defined unambiguously!

Lemma 2.6.

1. For $k > |V|$ or $k = 0$, we have: $\forall \alpha \in \mathbb{N} : \Lambda_{k,\alpha}(V, \cdot) = \emptyset$.
2. For $k \in \llbracket 1, |V| \rrbracket$ and $\alpha > \left\lfloor \frac{|V|}{k} \right\rfloor$, we have $\Lambda_{k,\alpha}(V, \cdot) = \emptyset$.

Proof.

1. For $k > |V|$ or $k = 0$, it is obvious that: $\Lambda_k(V, \cdot) = \emptyset$ (and then $\Lambda_{k,\alpha}(V, \cdot) = \emptyset$ as well).
2. Take such k and α . Assume (*ad absurdum*) that there exists $\Gamma \in \Lambda_{k,\alpha}(V, \cdot)$. We have then $L_1, \dots, L_\alpha \in \mathcal{P}(V)$ such that $\forall i \in \llbracket 1, \alpha \rrbracket : |L_i| = k$. Also, since the L_i 's are connected component, they are disjoint, i.e. $\forall (i, j) \in \llbracket 1, \alpha \rrbracket^2 : i \neq j \Rightarrow L_i \cap L_j = \emptyset$.

Thus $\bigsqcup_{i=1}^\alpha L_i \subseteq V$, and $\sum_{i=1}^\alpha |L_i| = k\alpha \leq |V|$

If $|V| \in k\mathbb{N}$, we have:

$$\alpha k > \left\lfloor \frac{|V|}{k} \right\rfloor k = |V|,$$

which yields a contradiction: $|V| > |V|$.

If $|V| \notin k\mathbb{N}$, we have:

$$\alpha > \left\lfloor \frac{|V|}{k} \right\rfloor \Rightarrow \alpha \geq \left(\left\lfloor \frac{|V|}{k} \right\rfloor + 1 \right),$$

and as $\lfloor |V|/k \rfloor k > |V| - k$, we have:

$$\alpha k \geq \left(\left\lfloor \frac{|V|}{k} \right\rfloor + 1 \right) k > |V| - k + k > |V|,$$

which yields the same contradiction.

We deduce that $\Lambda_{k,\alpha}(V, \cdot) = \emptyset$.

□

Corollary 2.7.

$$\forall k < |V| : \Lambda_k(V, \cdot) = \bigsqcup_{m=k-1}^{X(|V|)} \bigsqcup_{\alpha=1}^{\left\lfloor \frac{|V|}{k} \right\rfloor} \Lambda_{k,\alpha}^m(V, \cdot).$$

Proof. Unions are trivially disjoint.

Now show the equality. The right-hand side is trivially included in $\Lambda_k(V, \cdot)$ (by definition of $\Lambda_{k,\alpha}^m(V, \cdot)$).

Now take $\Gamma = (V, E) \in \Lambda_k(V, \cdot)$. We know that $\Gamma \in \Lambda_k^{|E|}(V, \cdot)$ with $|E| \leq X(|V|)$. As well, we know that the amount of connected components of size $|LCC(\Gamma)| = k$ is at least 1 (because $\Gamma \in \Lambda_k(V, \cdot)$), and lower or equal to $\left\lfloor \frac{|V|}{k} \right\rfloor$ by previous Lemma. □

2.6 The Set $\mathfrak{Q}_{k,\alpha}^m(V)$

Definition 2.8. For $k, \alpha \in \mathbb{N}^*$, let's define:

$$\mathcal{P}_{k,\alpha}(V) := \left\{ \{W_1, \dots, W_\alpha\} \in \mathcal{P}(\mathcal{P}(V)) \text{ s.t. } \begin{cases} \forall i \in \llbracket 1, \alpha \rrbracket : |W_i| = k \\ \forall (i, j) \in \llbracket 1, \alpha \rrbracket^2 : i \neq j \Leftrightarrow W_i \cap W_j = \emptyset \end{cases} \right\},$$

thus $\mathcal{P}_{k,\alpha}(V)$ is the set of all sets containing α subsets of V which are disjoint and of size k .

Remark. We can tell:

$$|\mathcal{P}_{k,\alpha}(V)| = \frac{1}{\alpha!} \prod_{\beta=0}^{\alpha-1} \binom{|V| - k\beta}{k} = \frac{1}{\alpha!} \frac{|V|!}{(k!)^\alpha (|V| - k\alpha)!}.$$

Definition 2.9. For $k \in \llbracket 1, |V| \rrbracket$, $m \in \llbracket 0, X(|V|) \rrbracket$, and $\alpha \in \llbracket 2, \lfloor \frac{|V|}{k} \rrbracket \rrbracket$, let's define:

$$\begin{aligned} \mathfrak{Q}_{k,\alpha}^m(V) &:= \bigsqcup_{\substack{\{W_1, \dots, W_\alpha\} \in \mathcal{P}_{k,\alpha}(V) \\ \mu(W_1) < \dots < \mu(W_\alpha)}} \bigsqcup_{\substack{(i_1, \dots, i_\alpha) \in \llbracket k-1, X(k) \rrbracket^\alpha \\ \text{s.t. } \sum_{j=1}^\alpha i_j \leq \min(m, \alpha X(k))}} \left[\left(\prod_{j=1}^\alpha \chi_{i_j}(W_j, \cdot) \right) \times \left(\bigsqcup_{p=1}^{k-1} \Lambda_p^{m - \sum_{j=1}^\alpha i_j} \left(V \setminus \bigsqcup_{j=1}^\alpha W_j, \cdot \right) \right) \right] \\ &= \bigsqcup_{\substack{\{W_1, \dots, W_\alpha\} \in \mathcal{P}_{k,\alpha}(V) \\ \mu(W_1) < \dots < \mu(W_\alpha)}} \bigsqcup_{\substack{\Sigma = \alpha(k-1) \\ (i_1, \dots, i_\alpha) \in \llbracket k-1, X(k) \rrbracket^\alpha \\ \text{s.t. } \sum_{j=1}^\alpha i_j = \Sigma}}^{\min(m, \alpha X(k))} \left[\left(\prod_{j=1}^\alpha \chi_{i_j}(W_j, \cdot) \right) \times \left(\bigsqcup_{p=1}^{k-1} \Lambda_p^{m - \Sigma} \left(V \setminus \bigsqcup_{j=1}^\alpha W_j, \cdot \right) \right) \right] \end{aligned}$$

Theorem 2.10. For $(k, m) \in \llbracket 1, |V| \rrbracket \times \llbracket 0, X(|V|) \rrbracket$ and $\alpha \in \llbracket 1, \lfloor \frac{|V|}{k} \rrbracket \rrbracket$, there exists a bijection between $\Lambda_{k,\alpha}^m(V, \cdot)$ and $\mathfrak{Q}_{k,\alpha}^m(V)$.

Proof. For such k, m, α , we have the function:

$$\begin{aligned} \Omega_\alpha : \Lambda_{k,\alpha}^m(V, \cdot) &\rightarrow \mathfrak{Q}_{k,\alpha}^m(V) : \\ \Gamma &\mapsto \left(\Delta_{W_1}(\Gamma), \dots, \Delta_{W_\alpha}(\Gamma), \Delta_{V \setminus \bigsqcup_{j=1}^\alpha W_j}(\Gamma) \right), \end{aligned}$$

for W_1, \dots, W_α the subsets of V two by two disjoint, such that $\forall i \in \llbracket 1, \alpha \rrbracket : |W_i| = k$, and that:

$$\forall i \in \llbracket 2, \alpha \rrbracket : \mu(W_{i-1}) \leq \mu(W_i).$$

We know that W_1, \dots, W_α are the only connected components of size k because $\Gamma \in \Lambda_{k,\alpha}^m(V, \cdot)$. And also, values of $\mu(W_j)$ can't be equal for different indices by definition of connected components. This implies that function Ω_α is properly defined.

Also, we notice that for a graph Γ , $\Omega(\Gamma)$ provides a partition of Γ by the definition of connected components.

Now, prove that Ω_α is bijective.

Injective Take $\Gamma_1 = (V, E_1), \Gamma_2 = (V, E_2) \in \Lambda_{k,\alpha}^m(V, \cdot)$. Let's assume that:

$$\Omega_\alpha(\Gamma_1) = \Omega_\alpha(\Gamma_2).$$

We can deduce that Γ_1 and Γ_2 have the same connected components, and that their restrictions to these connected components are equal as well. Thus we know that $V(\Gamma_1) = V(\Gamma_2)$ and $E(\Gamma_1) = E(\Gamma_2)$. Thus Γ_1 and Γ_2 must be equal.

Surjective Take:

$$(\Gamma_1 = (W_1, E_1), \dots, \Gamma_\alpha = (W_\alpha, E_\alpha), \Gamma = (W, E)) \in \mathfrak{Q}_{k,\alpha}^m(V),$$

and prove that there exists a graph $\hat{\Gamma} = (V, \hat{E}) \in \Lambda_{k,\alpha}^m(V, \cdot)$ such that:

$$\Omega_\alpha(\hat{\Gamma}) = (\Gamma_1, \dots, \Gamma_\alpha, \Gamma).$$

We know that $\{W_1, \dots, W_\alpha\} \in \mathcal{P}_{k,\alpha}(V)$ by definition of $\mathfrak{Q}_{k,\alpha}^m(V)$, and that:

$$V = W \sqcup \bigsqcup_{j=1}^{\alpha} W_j.$$

As well, by definition of $\mathfrak{Q}_{k,\alpha}^m(V)$, we know that if $\hat{E} := E \sqcup \bigsqcup_{j=1}^{\alpha} E_j$, then $|\hat{E}| = m$. So $\hat{\Gamma}$, the graph created by assembling the different components Γ_1 to Γ_α and Γ , is indeed in $\Lambda_{k,\alpha}^m$ because:

$$\forall j \in \llbracket 1, \alpha \rrbracket : |\text{LCC}(\Gamma_j)| = k \quad \text{and} \quad |\text{LCC}(\Gamma)| \leq k$$

by definition of $\mathfrak{Q}_{k,\alpha}^m(V)$.

Finally, $\Omega_\alpha(\hat{\Gamma})$ yields indeed $(\Gamma_1, \dots, \Gamma_\alpha, \Gamma)$ since connected components are ordered according to the μ function defined in Definition 1.10 \square

Remark. The problem of the largest connected component size has been reduced to a problem of connected graphs and recursive combinatorics.

Recursive values like these ones can be computed pretty efficiently thanks to dynamic programming.

3 Counting connected graphs

3.1 Connected graphs of $|V|$ vertices

Harary and Palmer proposed a solution in [1] in 1973 to the number of connected graphs of n vertices, no matter the number of edges.

Definition 3.1. For notations to be consistent with [1], let's define:

$$\forall p \in \mathbb{N} : C_p := \chi(p),$$

the number of connected graphs having p vertices.

Let's state the following theorem from [1], pages 7-8.

Theorem 3.2 (Harary and Palmer). *For all $p \in \mathbb{N}^*$, the number of connected graphs of p vertices is given by:*

$$C_p = \sum_{k=1}^{p-1} \binom{p-2}{k-1} (2^k - 1) C_k C_{p-k}.$$

The second equality stands as well:

$$C_p = 2^{\chi(p)} - \frac{1}{p} \sum_{k=1}^{p-1} k \binom{p}{k} 2^{\chi(p-k)} C_k.$$

3.2 Connected graphs of $|V|$ vertices and m edges

Yet, in definition of set $\mathfrak{Q}_{k,\alpha}^m(V)$, it is the cardinality of $\chi_\ell(n)$ that is needed, i.e. C_p is not sufficient.

Definition 3.3. Again, in order to stay consistent with cited references, let's denote:

$$\forall n \in \mathbb{N}^* : \forall k \in \llbracket 0, X(n) \rrbracket : q_{n,k} := |\chi_k(n)|.$$

Starting from generating function equality given by Bona and Noy in [2], namely:

$$\sum_{n \geq 0} \sum_{k \geq 0} q_{n,k} u^k \frac{z^n}{n!} = \log \left(\sum_{n \geq 0} (1+u)^{X(n)} \frac{z^n}{n!} \right),$$

one can find the recursion relation given by Marko Riedel [3]:

$$q_{n,k} = \binom{X(n)}{k} - \sum_{m=0}^{n-2} \binom{n-1}{m} \sum_{p=0}^k \binom{X(n-m-1)}{p} q_{m+1,k-p}.$$

4 Conclusion

We have then proved that the cardinality of set $\Lambda_k^m(V, \cdot)$ is equal to:

$$\begin{aligned} |\Lambda_k^m(V, \cdot)| &= \left| \bigcup_{\alpha=1}^{\lfloor \frac{|V|}{k} \rfloor} \Lambda_{k,\alpha}^m(V, \cdot) \right| = \sum_{\alpha=1}^{\lfloor \frac{|V|}{k} \rfloor} |\Lambda_{k,\alpha}^m(V, \cdot)| = \sum_{\alpha=1}^{\lfloor \frac{|V|}{k} \rfloor} |\mathfrak{A}_{k,\alpha}^m(V)| \\ &= \sum_{\alpha=1}^{\lfloor \frac{|V|}{k} \rfloor} |\mathcal{P}_{k,\alpha}(V)| \sum_{\Sigma=\alpha(k-1)}^{\min(m, \alpha X(k))} \sum_{\substack{(i_1, \dots, i_\alpha) \in \llbracket k-1, X(k) \rrbracket^\alpha \\ \sum_{j=1}^{\alpha} i_j = \Sigma}} \left(\prod_{j=1}^{\alpha} q_{i_j, k} \times \sum_{p=1}^{k-1} |\Lambda_p^{m-\Sigma}(|V| - k\alpha)| \right), \end{aligned}$$

from which we eventually deduce:

$$\forall k \in \llbracket 1, |V| \rrbracket : \mathbb{P} \left[|\text{LCC}(\mathcal{G}(V, m))| = k \right] = \frac{|\Lambda_k^m(V, \cdot)|}{|\Gamma_m(V, \cdot)|}.$$
