#### 1 Introduction

#### 1.1 Definitions and preliminary results

Let's consider  $V = \{v_1, \dots, v_{|V|}\}$  a set of vertices. We denote by |V| the cardinality of the set V. Let's define the function:

$$X: \mathbb{N} \to \mathbb{N}: \mathfrak{n} \mapsto \frac{\mathfrak{n}(\mathfrak{n}-1)}{2}.$$

**Definition 1.1.** An undirected graph  $\Gamma$  is denoted  $\Gamma(V,E)$  for V its vertices set, and E its edges set, with  $E = \{e_1, \ldots, e_{|E|}\}$  and  $\forall i \in [\![1,|E|]\!]$ :  $e_i = \{v_{i1},v_{i2}\}$  for  $1 \le i_1,i_2 \le |V|$  with  $i_1 \ne i_2$  (i.e. loops are not tolerated). *Remark.* |E| is usually denoted as m, and |V| is sometimes denoted as n. Both these numbers are (non-strictly) positive integers.

**Definition 1.2.** The set of all the existing graphs having given vertices set V is denoted by  $\Gamma(V, \cdot)$ . We denote  $\Gamma_{\mathfrak{m}}(V, \cdot)$  the subset of  $\Gamma(V, \cdot)$  such that  $|E| = \mathfrak{m}$ . *Remark.* We observe that:

$$\Gamma(V,\cdot) = \bigsqcup_{\mathfrak{m} \in \mathbb{N}} \Gamma_{\mathfrak{m}}(V,\cdot).$$

**Definition 1.3.** For every  $n \in \mathbb{N}$ , we define  $\mathcal{K}_n$  as the *complete graph* of size n.

*Proof.* We know that  $\Gamma(V, E) \leqslant \mathfrak{K}_{|V|}$ , and  $\mathfrak{K}_{|V|}$  has exactly X(V) edges (vertex  $v_i$  is connected to vertices  $v_{i+1}$  to  $v_{|V|}$ , so the number of edges is equal to  $\sum_{i=1}^{|V|} (|V|-i) = \sum_{i=0}^{|V|-1} i = X(|V|)$ .

**Lemma 1.5.** For given vertices set V and fixed number of edges  $m \in \mathbb{N}$ , we have:

$$\left|\Gamma_{\mathfrak{m}}(V,\cdot)\right| = \begin{cases} \binom{X(|V|)}{\mathfrak{m}} & \text{if } \mathfrak{m} \leqslant X(|V|) \\ 0 & \text{else} \end{cases}.$$

**Corollary 1.6.** For given vertices set V, we have  $|\Gamma(V, \cdot)| = 2^{X(|V|)}$ .

*Proof.* Since  $\Gamma(V, \cdot)$  is given by a disjoint union over m, its cardinality is equal to the sum of the individual cardinalities:

$$\left|\Gamma(V,\cdot)\right| = \sum_{\mathfrak{m} \in \mathbb{N}} \left|\Gamma_{\mathfrak{m}}(V,\cdot)\right| = \sum_{k=0}^{X(|V|)} \left|\Gamma_{\mathfrak{m}}(V,\cdot)\right| = \sum_{k=0}^{X(|V|)} \binom{X(|V|)}{\mathfrak{m}} = 2^{X(|V|)}.$$

**Definition 1.7.** A graph  $\Gamma(V, E)$  is said to be connected if for each  $v, w \in V$ , there exists a path between v and w. We denote by  $\chi(V, \cdot)$  the set of all connected graphs having vertices set V. Again, for  $\mathfrak{m} \in \mathbb{N}$ , we denote by  $\chi_{\mathfrak{m}}(V, \cdot) \subset \chi(V, \cdot)$  the set of connected graphs having  $\mathfrak{m}$  edges. *Remark.*  $\chi(V, \cdot) \subset \Gamma(V, \cdot)$ , and:

$$\chi(V,\cdot) = \bigsqcup_{m \in \mathbb{N}} \chi_m(V,\cdot).$$

**Lemma 1.8.** For m < |V| or m > X(|V|), we have  $|\chi_m(V, \cdot)| = 0$ .

**Definition 1.9.** For every  $W \in \mathcal{P}(V)$ , we define  $\Delta_W : \Gamma(V, \cdot) \to \Gamma(W, \cdot) : \Gamma(V, E) \mapsto \Gamma'(W, E')$  such that:

$$\mathsf{E}' = \left\{ \{v_{\mathfrak{i}}, v_{\mathfrak{j}}\} \in \mathsf{E} \text{ s.t.} v_{\mathfrak{i}}, v_{\mathfrak{j}} \in W \right\}.$$

**Definition 1.10.** We define the *connected component of vertex*  $v_i \in V$  *in graph*  $\Gamma(V, E)$  by the biggest subset (in the sense of inclusion) W of V such that  $v_i \in W$  and  $\Delta_W(\Gamma(V, E)) \in \chi(W, \cdot)$ .

For graph  $\Gamma(V, E) \in \Gamma(V, \cdot)$ , we define  $|LCC(\Gamma(V, E))|$  by:

$$|LCC(\Gamma(V, E)| := \max_{W \in \mathcal{P}(V)} |W| \mathbb{I}_{[\Delta_W(\Gamma(V, E) \in \chi(V, \cdot)]}.$$

We then define the *largest connected component of the graph*  $\Gamma(V, E)$  as:

$$LCC(\Gamma(V,E)) \coloneqq \mathop{arg\,min}_{\substack{W \in \mathcal{P}(V) \\ |W| = \left|LCC(\Gamma(V,E))\right|}} \mathop{min}_{i \in \llbracket 1,|V| \rrbracket} i \times \mathbb{I}_{[\nu_i \in W]}.$$

The set  $\Lambda_k^m(V,\cdot)$  is then the set of all graphs  $\Gamma(V,E)\in\Gamma(V,\cdot)$ , such that |E|=m and  $|LCC(\Gamma(V,E))|=k$ . *Remark.* The notations here are consistent since  $|LCC(\Gamma(V,E))|$  corresponds indeed to the cardinality of  $LCC(\Gamma(V,E))$ .

Furthermore, this definition of largest connected component allows to define uniquely the LCC, even though a graph  $\Gamma(V, E)$  has several connected component of same size. For example, following graph has two connected component of size 2, i.e.  $\{1,2\}$  (in red) and  $\{3,4\}$  (in blue).

Figure 1: Graph  $\Gamma(\{1,2,3,4\},\{\{1,2\},\{3,4\}\})$ 

Nevertheless, the LCC operator yields {1,2} since it minimizes the lowest id of element in connected component (1 for this graph).

*Remark.* Since  $\Lambda_k(V,\cdot) = \bigsqcup_{m=0}^{X(|V|)} \Lambda_k^m(V,\cdot)$  and:

$$\Gamma(V,\cdot) = \bigsqcup_{k=1}^{|V|} \bigsqcup_{m=0}^{X(|V|)} \Lambda_k^m(V,\cdot),$$

we want to know what is  $|\Lambda_k^{\mathfrak{m}}(V,\cdot)|$  equal to.

**Definition 1.11.** Let's declare a new random variable  $\mathcal{G}(V)$ , a graph uniformly distributed in  $\Gamma(V, \cdot)$ , thus such that:

$$\forall \Gamma(V,E) \in \Gamma(V,\cdot): \mathbb{P}[\mathscr{G}(V) = \Gamma(V,E)] = \frac{1}{\left|\Gamma(V,\cdot)\right|} = 2^{-X(|V|)}.$$

# 1.2 Objectives

The objective now is to find an expression for  $|\Lambda_k(V,\cdot)|$  since we are looking for:

$$\mathbb{P}\left[LCC(\mathscr{G}(V)) = k\right] = \frac{\left|\Lambda_k(V,\cdot)\right|}{\left|\Gamma(V,\cdot)\right|} = \frac{1}{\left|\Gamma(V,E)\right|} \sum_{m=0}^{X(|V|)} \left|\Lambda_k^m(V,\cdot)\right|.$$

Let's denote this value  $\mathfrak{p}_k \coloneqq \mathbb{P}\left[\left|LCC(\mathscr{G}(V))\right| = k\right].$ 

#### 2 Results

The general idea in order to determine  $|\Lambda_k^m(V,\cdot)|$  is to insert a connected component of size k on vertices set V, and then to tally the configurations placing m-k vertices without making a bigger connected component than the first one.

# 2.1 Examples

**2.1.1** 
$$\left| \Lambda_{k=1}(V, \cdot) \right|$$

It is trivial to tell  $|\Lambda_1^{\mathfrak{m}}(V,\cdot)| = \delta_0^{\mathfrak{m}}$ , i.e. equals one if  $\mathfrak{m} = 0$  and equals zero if  $\mathfrak{m} > 0$ : a graph having at least one edge, cannot have a largest connected component of size 1.

#### **2.1.2** Upper boundary of m for $|\Lambda_k^m(V, \cdot)|$

**Lemma 2.1** (Upper boundary of edges amount for k=2). For  $m>\frac{|V|}{2}$ , we have  $\Lambda_2^m(V,\cdot)=\emptyset$ .

*Proof.* To have a largest connected component of size 2, each vertex must have degree 0 or 1. Take  $m \in \mathbb{N}$  such that  $m > \frac{V}{2}$ . Take  $\Gamma(V, E)$  such that |E| = m, and take  $V_1 := \{v \in V \text{ s.t. deg}(v) \leq 1\} \subset V$ . Take the restriction  $\Gamma'(V_1, E') = \Delta_{V_1}(\Gamma(V, E))$ .

Since in a graph, the sum of the degree of each vertex is equal to twice the amount of edges, when applied on  $\Gamma'$ , it follows that:

$$2\big|\mathsf{E}'\big| = \sum_{\nu \in \mathcal{V}_1} \mathsf{deg}(\nu) \leqslant \sum_{\nu \in \mathcal{V}_1} 1 = |\mathcal{V}_1|\,.$$

We then deduce that  $|E'| \le \frac{|V_1|}{2} \le \frac{|V|}{2}$ . Thus  $V_1$  must be *strictly* included in V, and then there must exist  $v \in V$  such that  $deg(v) \ge 2$ . Thus:

$$\forall m > \frac{|V|}{2} : \forall \Gamma(V, E) \in \Gamma_{m}(V, \cdot) : \Gamma(V, E) \not\in \Lambda_{2}^{m}(V, \cdot).$$

**Lemma 2.2.** For  $\Gamma(V,E) \in \Gamma(V,\cdot)$  a graph and  $k \in [1,|V|]$ , if there exists a vertex  $v \in V$  such that deg(v) = k, then  $|LCC(\Gamma(V,E))| \geqslant k+1$ .

*Proof.* Take  $v \in V$  such that deg(v) = k. There exist  $\{v_{i_1}, \dots, v_{i_k}\} \subset V$  such that:

$$\forall j \in [\![1,\,k]\!]: \{\nu,\nu_{\mathfrak{i}_{\mathfrak{j}}}\} \in E.$$

Thus  $\{v, v_{i_1}, \dots, v_{i_k}\}$  is a connected component of size k+1. Thus the largest connected component must have size at least that big.

**Proposition 2.3** (Upper boundary of edges amount generalized). For  $k \in [1, |V|]$ , and  $m > \frac{|V|(k-1)}{2}$ , we have  $\Lambda_k^m(V, \cdot) = \emptyset$ .

*Proof.* Take  $m > \frac{(k-1)|V|}{2}$ , and  $\Gamma(V,E) \in \Gamma_m(V,\cdot)$ . Take  $\mathcal{V}_k \coloneqq \{ \nu \in V \text{ s.t. deg}(\nu) \leqslant k-1 \}$ . Let  $\Gamma'(\mathcal{V}_k,E')$  be defined by  $\Delta_{\mathcal{V}_k}(\Gamma(V,E))$ . We know that:

$$2\big|\mathsf{E}'\big| = \sum_{\nu \in \mathcal{V}_k} deg(\nu) \leqslant (k-1)|\mathcal{V}_k| \leqslant (k-1)|V|\,.$$

We deduce that  $|E'| \leqslant \frac{(k-1)|V|}{2} < m = |E|$ . Thus  $|E| \ngeq |E'|$ , and this implies that there exists  $v \in V$  such that  $deg(v) \geqslant k$ . By previous lemma, largest connected component size must be at least k+1.

*Remark.* We can understand this upper boundary as  $m > \frac{|V|(k-1)}{2} = \frac{|V|}{k} \frac{k(k-1)}{2} = \frac{|V|}{k} \cdot X(k)$ . So in order to have a LCC of size k, edges can be distributed to make  $\left\lfloor \frac{|V|}{k} \right\rfloor$  complete graphs having each X(k) edges. The maximum amount of edges is then given by  $\frac{|V|(k-1)}{2}$ .

**2.1.3** 
$$|\Lambda_{k=2}(V,\cdot)|$$

Example of size 2 is a bit more complicated:

$$\forall m \in \left[\!\left[1, \, \left\lfloor \frac{|V|}{2} \right\rfloor \right]\!\right] : \left|\Lambda_2^m(V, \cdot)\right| = \begin{cases} \frac{1}{m!} \prod_{k=0}^{m-1} \binom{|V|-2k}{2} & \text{if } m \leqslant \frac{|V|}{2} \\ 0 & \text{else} \end{cases}.$$

*Proof.* For  $m > \frac{|V|}{2}$ , result is shown in Lemma 2.1. The part  $\prod_{k=0}^{m-1} \binom{|V|-2k}{2}$  corresponds to the choice of m edges without making a connected component of size  $\geqslant 3$ .

 $\binom{|V|-2\cdot 0}{2}$  is the choice of the first edge (two vertices) among |V| vertices,  $\binom{|V|-2}{2}$  is the choice of the second edge (two vertices) among the |V|-2 vertices left, etc. At step  $\ell$ , only  $|V|-2(\ell-1)$  vertices are available because two are selected per step, and a selected vertex cannot be used again, otherwise its degree would be  $\geqslant 2$ , and then the largest component size would be  $\geqslant 3$ .

The  $\frac{1}{m!}$  comes from the fact that the order the edges are selected doesn't matter (so for each choice of m edges, there are m! permutations of these).

Remark. This can also be expressed as:

$$\left|\Lambda_2^{\mathfrak{m}}(V,\cdot)\right| = \frac{1}{\mathfrak{m}!} \frac{|V|!}{2^{\mathfrak{m}} \left( V | - 2\mathfrak{m} \right)!},$$

by simplification of the product.

# 3 Processing on examples

$$\begin{split} \left| \Lambda_3^0(V, \cdot) \right| &= \left| \Lambda_3^1(V, \cdot) \right| = 0 \\ \left| \Lambda_3^2(V, \cdot) \right| &= \binom{|V|}{3} \binom{3}{2} \\ \left| \Lambda_3^3(V, \cdot) \right| &= \binom{|V|}{3} \binom{3}{3} + \binom{|V|}{3} \binom{3}{2} \binom{|V| - 3}{2} \\ \left| \Lambda_3^4(V, \cdot) \right| &= \binom{|V|}{3} \binom{3}{3} \binom{|V| - 3}{2} + \binom{|V|}{3} \binom{3}{2} \binom{|V| - 3}{3} \binom{3}{2} + \binom{|V|}{3} \binom{3}{2} \binom{|V| - 3}{2} \binom{|V| - 5}{2}. \end{split}$$

**Definition 3.1.** Let's denote equally  $|\Lambda_k^{\mathfrak{m}}(\mathfrak{n})| = \Lambda_k^{\mathfrak{m}}(\mathfrak{n}) \equiv |\Lambda_k^{\mathfrak{m}}(V,\cdot)|$  for V such that  $|V| = \mathfrak{n}$ .

This notation allows to lighten the expressions.

#### Conjecture 3.2.

$$\left|\Lambda_k^{\mathfrak{m}}(|V|)\right| = \binom{|V|}{k} \sum_{\ell=k-1}^{\min\left(\mathfrak{m},X(k)\right)} \left|\Lambda_k^{\ell}(k)\right| \sum_{\mathfrak{p}=1}^{k} \left|\Lambda_{\mathfrak{p}}^{\mathfrak{m}-\ell}(|V|-k)\right| \beta_{\mathfrak{p}\,\ell}(\mathfrak{m},k,|V|),$$

with  $\beta_{p\ell}(m, k, |V|)$ , a coefficient.

*Remark.* The idea behind this formula is explained in introduction of Section 2: to find the amount of graphs having n vertices, m edges and a largest connected component of size k, let's place a connected component of size k somewhere in the graph (so choose k in |V| vertices), and then multiply this by the amount of possible graphs of largest connected component of size  $p \in \{1, ..., k\}$  (so lower or equal to k).

*Idea of proof of conjecture.* In order to prove the equality of the cardinalities, let's find a bijective function  $\Omega$  between  $\Lambda_k^m(V,\cdot)$  and a set like:

$$\mathfrak{Q}_k^{\mathfrak{m}}(V) \coloneqq \bigsqcup_{\substack{W \in \mathfrak{P}(V) \\ |W| = k}} \bigsqcup_{\ell = k-1}^{\min\left(\mathfrak{m}, X(k)\right)} \Lambda_k^{\ell}(W, \cdot) \times \left(\bigsqcup_{\mathfrak{p} = 1}^k \Lambda_{\mathfrak{p}}^{\mathfrak{m} - \ell}(V \setminus W, \cdot)\right).$$

**Lemma 3.3.** The sets  $\chi_{\ell}(V,\cdot)$  and  $\Lambda_{|V|}^{\ell}(V,\cdot)$  are equal.

*Proof.* A graph  $\Gamma(V, E)$  is connected if and only if its largest connected component contains all its vertices, i.e.  $LCC(\Gamma(V, E)) = V$ .

This is equivalent to say that  $|LCC(\Gamma(V, E))| = |V|$  since  $\forall W \in \mathcal{P}(V) : |W| = |V| \Rightarrow V = W$ :

$$\forall W \in \mathcal{P}(V) : \left| \left\{ \widetilde{W} \in \mathcal{P}(V) \text{ s.t.} |W| = \left| \widetilde{W} \right| \right\} \right| = {|V| \choose |W|},$$

and  $\binom{|V|}{|V|} = 1$ , thus  $\{W \in \mathcal{P}(V) \text{ s.t.} |W| = |V|\} = \{V\}$ .

# 3.1 Decomposing set $\Lambda_k(V)$

**Definition 3.4.** For  $k \in \mathbb{N}$ , and  $\alpha \in \mathbb{N}$ , we define:

$$\Lambda_{k,\alpha}(V,\cdot) \coloneqq \left\{ \Gamma(V,\mathsf{E}) \in \Lambda_k(V,\cdot) \text{ s.t. } \left\{ W \in \mathcal{P}(V) \text{ s.t.} \Delta_W(\Gamma(V,\mathsf{E})) \in \chi(W) \text{ and } |W| = \left| LCC(\Gamma(V,\mathsf{E})) \right| \right\} = \alpha \right\},$$

the class of all graphs in  $\Lambda_k(V,\cdot)$  having exactly  $\alpha$  connected components of maximum size.

*Remark.* Even though several connected components of maximum size do exist in a graph, the one LCC is still defined unambiguously!

#### Lemma 3.5.

- 1. For k > |V| or k = 0, we have:  $\forall \alpha \in \mathbb{N} : \Lambda_{k,\alpha}(V, \cdot) = \emptyset$ .
- 2. For  $k \in [\![1,|V|]\!]$  and  $\alpha > \left\lfloor \frac{|V|}{k} \right\rfloor$ , we have  $\Lambda_{k,\alpha}(V,\cdot) = \emptyset$ .

Proof.

- 1. For k>|V| or k=0, it is obvious that:  $\Lambda_k(V,\cdot)=\emptyset$  (and then  $\Lambda_{k,\alpha}(V,\cdot)$ ).
- 2. Take such k and  $\alpha$ . Assume (ad absurdum) that there exists  $\Gamma(V,E) \in \Lambda_{k,\alpha}(V,\cdot)$ . We have then  $L_1,\ldots,L_\alpha \in \mathcal{P}(V)$  such that  $\forall i \in \llbracket 1,\alpha \rrbracket : |L_i|=k$ . Also, since the  $L_i$ 's are connected component, they are disjoint, i.e.  $\forall (i,j) \in \llbracket 1,\alpha \rrbracket^2 : i \neq j \Rightarrow L_i \cap L_j = \emptyset$ .

Thus  $\bigcup_{i=1}^{\alpha}L_{i}\subset V$  , and  $\sum_{i=1}^{\alpha}\lvert L_{i}\rvert\leqslant\lvert V\rvert.$  But:

$$\sum_{i=1}^{\alpha} |L_i| = \alpha k > \left\lfloor \frac{|V|}{k} \right\rfloor k > \frac{|V|}{k} k = |V|,$$

which leads a contradiction: |V| > |V|. We deduce that  $\Lambda_{k,\alpha}(V,\cdot) = \emptyset$ .

 $\textit{Remark}. \ \, \text{Again, for } \mathfrak{m} \in \big[\![1,X(\![V])]\!] \text{, we define } \Lambda^{\mathfrak{m}}_{k,\alpha}(V,\cdot) \text{ by } \Lambda^{\mathfrak{m}}_{k}(V,\cdot) \cap \Lambda_{k,\alpha}(V,\cdot).$ 

Corollary 3.6.

$$\forall k < \! |V| : \Lambda_k(V, \cdot) = \bigsqcup_{m=k-1}^{X(\! |V|)} \bigsqcup_{\alpha=1}^{\left \lfloor \frac{|V|}{k} \right \rfloor} \Lambda_{k,\alpha}^m(V, \cdot).$$

*Proof.* Unions are trivially disjointed.

Now show the equality. The right-hand side is trivially included in  $\Lambda_k(V,\cdot)$  (by definition of  $\Lambda_{k,\alpha}^{\mathfrak{m}}(V,\cdot)$ ).

now take  $\Gamma(V,E) \in \Lambda_k(V,\cdot)$ . We know that  $\Lambda_k^{|E|}(V,\cdot)$  with  $|E| \leqslant X(|V|)$ . As well, we know that the amount of connected components of size  $\left|LCC(\Gamma(V,E))\right| = k$  is at least 1 (because  $\Gamma(V,E) \in \Lambda_k(V,\cdot)$ ), and lower or equal to  $\left\lfloor \frac{|V|}{k} \right\rfloor$  by previous Lemma.
